

GaNPower demonstrates high voltage switching at 120A

GaNPower recently released its 60A and 120A bare die series [link_to_product_page] GaNFET and GaN-IC at a voltage rating of 650V/900V, which includes options to drive the Emode GaNFET at the original gate voltage of 6V [G0(6V)] or 12/15V [G1(15V)]. We are pleased to inform that the proprietary gate regulator GaN-IC worked well and we have demonstrated that using $V_g=0$ to 12V driving at $V_{bus}=500V$ or above, a max current of 120A can be switched successfully at about 100KHz frequency. The demo packaging was done using TO247-4 with pin-out compatible with conventional IGBT/MOSFET/SiC with lead sequence of D-S-KS-G. This is good news for customers wishing to design power modules for automotive traction driver. Specifically, three or four pairs of the 120A dies would enable the max current needed for EV traction driver.

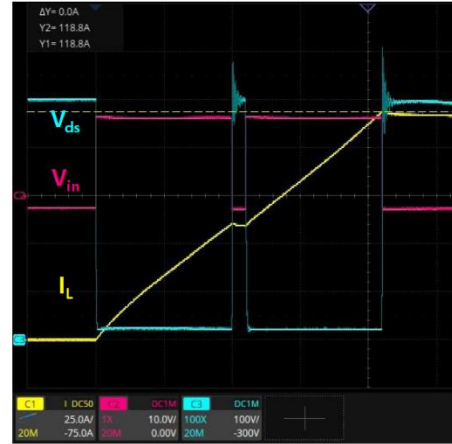

Dynamic Testing Double Pulse Testing up to 500V 120A

400V 120A Double Pulse

500V 120A Double Pulse

Double pulse testing results of GPI650120T4 in TO247-4 package. Switching frequency approximately 100KHz and V_g 0 to 12V driving.
